

# EL9343 Homework 12

Due: Dec. 15th 11:00 a.m.

- Consider the following graph, with node 0 as the source node.
  - Run Dijkstra's algorithm. Write down the  $d$  array before each EXTRACT-MIN, also the final array.
  - Run Bellman-Ford algorithm. Write down the  $d$  distance array after each pass.

- Run the Floyd-Warshall algorithm on the following graph. Show the matrix  $D^{(k)}$  that results for each iteration of the outer loop.

- Let  $G(V, E)$  be a directed, weighted graph. The goal is to find the shortest path from a source node  $s$  to every nodes in the graph.
  - If all edges have unit weight, is there an algorithm faster than Dijkstra? Please just state the algorithm and its running time.
  - Now suppose the weight function has the form  $w(\cdot) : E \rightarrow \{1, 2\}$ , i.e. every edge has weight either 1 or 2. Design  $O(|V| + |E|)$ -time algorithm for the problem. Please show why your algorithm works and how to get the running time bound.
- The goal of this problem is to travel from home to a store, purchase a gift, and then get back home, at minimal cost.

Let us model this problem using a directed graph. Let  $G(V, E)$  be a directed, weighted graph, with non-negative edge weights  $w : E \rightarrow \mathbb{R}^+$ . The weight of an edge represents the cost of traversing that edge. Each vertex  $v \in V$  also has an associated cost  $c(v) \in \mathbb{R}^+$  which represents the cost of purchasing the desired gift at that location.

Starting from "home base"  $h \in V$ , the goal is to find a location  $v \in V$  where the gift can be purchased, along with a path  $p$  from  $h$  to  $v$  and back from  $v$  to  $h$ . The cost of such a solution is the cost  $c(v)$  of the location  $v$  plus the weight  $w(p)$  of the path  $p$  (i.e., the sum of edge weights along the path  $p$ ).

Design an algorithm that on input  $G(V, E)$ , including edge weights  $w(\cdot)$  and costs  $c(\cdot)$ , and home base  $h \in V$ , finds a minimal cost solution. Assuming  $G$  is represented using adjacency lists, and Dijkstra's algorithm runs in  $O(|E| \log |V|)$ . Your algorithm should run Dijkstra **exactly once** and in time  $O((|V| + |E|) \log |V|)$ . Please show why your algorithm works and analyze the time complexity.

**Hints:** If you try to solve with the original graph  $G$ , then most likely you will have to run multiple times of Dijkstra. You can try to extend the graph  $G$  into two layers. What is the number of nodes and edges?
